The simplex algorithm can then be applied to find the solution; this step is called Phase II. If the minimum is positive then

there is no feasible solution for the Phase I problem where the artificial variables are all zero. This implies that the feasible region for the original problem is empty, and so the original problem has no solution.

A greedy algorithm is any algorithm that follows the problem-solving heuristic of making the locally optimal choice at each stage. In many problems, a greedy strategy does not usually produce an optimal solution, but nonetheless, a greedy heuristic may yield locally optimal solutions that approximate a globally

... but this often requires an intuitive leap to understand the actual problem rather than the solution. For example, they do not often define terms used in questions, leaving the user to guess. Perhaps this should fall under the professor's domain, but it is still frustrating. The index is not great. The authors perhaps need ...

logic that, if graph has  $n$  nodes, then shortest path never contain more than  $n-1$  edges. This is exactly what Bellman-Ford do. It is enough to relax each edge  $(v-1)$  times to find shortest path. But to find whether there is negative cycle or not we again do one more relaxation. If we get less distance in  $n$ th relaxation we can say that
